Theorem

$$\forall \ \mathtt{exptree} \ \mathbf{e}$$

$$\mathtt{mk_big} \ (\mathtt{eval}(\mathtt{e})) = \mathtt{stackmc} \ \mathtt{li} \ (\mathtt{compile} \ \mathtt{e})$$

Proof

We shall be proving the theorem by applying induction on the height of exptree.

Base Case

The base case height for exptree is 0. In this case the tree e, is just N(x) for some int. In this case,

$$\label{eq:eval_eval} \begin{split} \text{eval(e)} &= x \; \text{and}, \\ \text{compile(e)} &= [\text{CONST(mk_big} \; x)] \end{split}$$

which after evaluation with stackmc would give

$$to tensor stack model in (compile e) = (mk_big x)$$

Thus, with this we can conclude

Inductive Hypothesis

Now, we assume that \forall exptree e with height(e) $\leq k$ satisfy the above theorem, i.e. mk_big (eval(e)) = stackmc li (compile e), where $k \geq 0$. [10 pt]

Inductive Step

Now, let e be an exptree with height = k + 1.

Now, since $k \geq 0$, height of $e \geq 1$.

This ensures that e is of the form (BIN of exptree*exptree) or (UN of exptree), where BIN and UN are binary and unary operations, respectively.

Case 1 (Binary Operation)

Now, e is of the form BIN(el, er). Since, el and er are subtrees of e their height is going to be $\leq k$. Thus, our induction hypothesis holds for these trees. Therefore,

```
mk\_big (eval(er)) = stackmc li (compile er) = mk\_big xr (say)
mk\_big (eval(el)) = stackmc li (compile el) = mk\_big xl (say)
```

Also,

Now, for LHS,

$$eval(e) = eval(el) ** eval(er), and so$$

 $eval(e) = xl ** xr$

where ** is the syntactic representation of BIN.

Now, for RHS

and, hence induction holds.

```
stackmc l1 (compile e) = stackmc l1 (compile el)@(compile er)@[BIN]
```

And, by the definition of stackmc, since compile el represents a complete tree, its values mk_big xl will be prepended to stack. The same goes for compile er. And, therefore,

```
stackmc l1 (compile e) = stackmc ((mk_big xr)::(mk_big xl)::l1) [BIN]
```

Now, following the definition of stackmc, the above expression evaluates to,

Case 2 (Unary Operation)

With most properties same as above, by induction hypothesis,

$$\label{eq:mk_big} \mbox{mk_big eval(e')} = \mbox{stackmc li (compile e')} = \mbox{mk_big x'} \ (\mbox{say})$$

Also,

Now, for LHS,

where # is the syntactic representation of UN.

Now, for RHS

And, by the definition of stackmc, since compile e' represents a complete tree, its values mk_big x' will be prepended to stack. And, therefore,

Now, following the definition of stackmc, the above expression evaluates to,

stackmc l1 (compile e) = UN (
$$mk_big x'$$
), which is same as UN ($mk_big x'$) = $mk_big (\#xr) = mk_big (eval(e)$

and, hence induction holds.

Thus, induction holds, and thus the theorem is correct.

Note

We have used some properties which are cleared here

- UN (mk_big x') = mk_big (#xr), from definition of UN in bigint
- BIN (mk_big xl) (mk_big xr) = mk_big (xl ** xr), from definition of BIN in bigint
